

PRESS RELEASE

Certus Launches Continuous Media Provenance for AI-Transformed Contact-Centre Speech Pipelines

Provider-agnostic provenance and integrity verification helps enterprises maintain verifiable evidence across AI speech transformations, communication channels and downstream media changes.

HYDERABAD, India - 23 Apr 2028 -Certus today announced the launch of its observational provenance layer for AI-processed contact-centre speech pipelines. Certus continuously records and verifies speech integrity across the processing pipeline, enabling enterprise contact-centre operators, CCaaS platforms and AI speech-processing providers to preserve a continuous, auditable record from source media through successive authorised AI transformations to downstream verification.

The Customer Problem

AI is increasingly used to intentionally transform contact-centre speech through capabilities such as noise cancellation, source separation, accent conversion and other speech enhancements. The resulting media may change further as it travels through telephony and network channels.

These changes create a new trust challenge for organisations operating AI-processed speech workflows. A difference between the source and received media does not, by itself, explain what changed, why it changed, whether the change was authorised, or where continuity was lost across the processing chain. As multiple AI-processing stages and providers become part of the same speech lifecycle, evidence can become fragmented across individual systems. Contact centres need a way to preserve that evidence continuously so that legitimate AI processing remains accountable, ordinary channel variation can be distinguished from unexplained changes, and potential unauthorised manipulation remains detectable.

The Solution

Certus creates a continuous provenance chain across the speech lifecycle. The platform establishes provenance at the source, records each authorised AI transformation through signed transformation evidence, maintains continuity between successive processing stages, and independently verifies the resulting media against the evidence accumulated throughout the lifecycle.

This enables organisations to answer three fundamental questions about AI-processed speech: **What happened to the media? Who or what was authorised to change it? Does the received media remain consistent with that history?**

When the observed media differs from the expected media, Certus follows an **evidence-before-inference** approach by evaluating provenance, authorised transformation evidence and available channel context to

determine whether the result represents an **Authorised Transformation, Benign Channel Variation, Integrity Indeterminate, or Suspected Unauthorised Manipulation**.

A Continuous Trust Layer Across Providers

Existing authentication, deepfake-detection, tamper-verification and source-provenance technologies address important individual parts of the media-trust problem. But AI-transformed speech can pass through multiple authorised processing stages before reaching its final destination.

Rather than requiring speech-processing providers to trust or integrate directly with one another, **each authorised transformation contributes signed evidence to the Certus provenance record**. This allows enterprises to preserve accountability across heterogeneous speech-processing environments while continuing to use the AI technologies and providers appropriate to their workflows.

Designed for the People Responsible for Speech Integrity

Contact-centre teams can use Certus to view the provenance status of processed speech, understand integrity outcomes and investigate exceptions without interpreting the underlying cryptography. Speech-processing providers can attest to the transformations they were authorised to perform, while Certus independently verifies continuity across the resulting evidence chain.

Where downstream systems such as speaker verification, speech recognition or fraud-detection platforms require additional context, Certus provenance can provide evidence that an authorised transformation occurred. Those systems can then determine how that evidence should influence their own decisions.

Company Quote

“AI-processed speech should be able to change without losing its history,” said **Aditi Moudgalya, Creator of Certus**. “As more AI systems participate in the speech lifecycle, organisations need to know not simply that media changed, **but how it changed, why it changed and whether those changes remain consistent with the authorised processing history**. Certus provides the continuous evidence layer designed to make that possible.”

Customer Quote

“As AI becomes a larger part of our speech-processing workflow, we need confidence that every authorised change remains traceable. Certus gives our teams one continuous provenance trail, making it easier to understand the history of the media without piecing together evidence from separate systems.”

— **John Doe, Chief Product Officer at Gen9**

Getting Started

Certus is available for enterprise contact-centre environments and integrates with supported speech-processing and contact-centre workflows as an independent provenance and verification layer. Customers can monitor provenance continuity, review integrity outcomes and investigate exceptions through role-based Certus dashboards.

For information about supported integrations and commercial plans, visit **Certus website link**.
